

Requirement Analysis

Requirement analysis is the process of identifying and understanding the needs of the system before developing the solution. In this project, the main requirement is to automate the ticket assignment process in order to improve efficiency in support operations.

ABC Corporation handles a large number of support tickets related to various products and services. Previously, the tickets were assigned manually by the support team, which caused delays and sometimes resulted in tickets being assigned to the wrong teams. This affected the overall efficiency of the support process and led to customer dissatisfaction.

To overcome these issues, the organization requires an automated ticket routing system within the ServiceNow platform. The system should be able to analyze the ticket details such as category, priority, or type of issue and automatically assign the ticket to the appropriate support group.

The key requirements of the system include creating users, defining support groups, assigning appropriate roles, and configuring assignment rules for automated ticket routing. The system should ensure that tickets reach the correct team quickly so that issues can be resolved faster.

By implementing this solution, ABC Corporation aims to reduce manual effort, improve response time, and increase customer satisfaction through efficient support operations.
