

Streamlining Ticket Assignment for Efficient Support Operations

Project Documentation

1. Introduction

Team Members:

- SHAHANA S
- SRIVITHYA A

- SPINO J

In modern organizations, technical support teams handle a large number of support requests every day. These requests are usually submitted in the form of support tickets which describe the problem faced by the user. Traditionally, these tickets are manually reviewed and assigned to the appropriate team by support administrators. However, as the number of products and services increases, manually assigning tickets becomes inefficient and time consuming. Delays in ticket assignment often lead to slower problem resolution and reduced customer satisfaction. This project focuses on designing an automated ticket assignment system that can intelligently route support tickets to the appropriate team based on the type of issue reported. By using the automation features available in ServiceNow, the system can analyze ticket information and assign it to the correct support group without human intervention. This significantly reduces response time and improves operational efficiency within the organization.

2. Project Overview

Purpose

The primary purpose of this project is to streamline support operations by introducing an automated ticket routing system. Instead of manually assigning each ticket, the system automatically identifies the category of the issue and routes the ticket to the appropriate team responsible for handling that type of problem. This ensures that tickets are processed quickly and accurately. In addition, the system also improves transparency and accountability within the support department because each ticket is tracked and assigned to a responsible group. The implementation of this automation reduces the workload of administrators and allows support staff to focus on solving technical issues rather than managing ticket distribution.

Key Features

- Automatic routing of support tickets to relevant support groups
- Centralized management of users, roles, and groups
- Role-based security to protect system data
- Custom tables to store operational ticket information
- Workflow automation using ServiceNow Flow Designer
- Improved efficiency and reduced manual effort
- Faster issue resolution and improved customer satisfaction

3. System Architecture

Frontend Layer

The frontend layer represents the user interface through which users interact with the system. This interface allows employees to create support tickets by selecting the issue type and providing relevant information about the problem. Administrators can also use the interface to manage users, roles, and support groups. The frontend provides dashboards and forms that display ticket status, assigned teams, and resolution progress.

Backend Layer

The backend layer processes the data submitted by users and executes the business logic responsible for ticket routing. When a ticket is created, the backend evaluates the issue category and determines which support group should handle the request. Automation workflows implemented using ServiceNow Flow Designer ensure that this process happens instantly and without manual intervention.

Database Layer

The database stores all relevant system information including user details, group information, roles and permissions, and ticket records. This structured storage allows the system to track ticket history, monitor support performance, and generate reports. Proper database management ensures that all ticket data is securely stored and easily accessible when needed.

4. Setup Instructions

Prerequisites

- Active ServiceNow instance
- Administrator privileges to configure the platform
- Basic knowledge of ServiceNow modules
- Stable internet connectivity

Implementation Steps

- 1 Login to the ServiceNow platform using administrator credentials
- 2 Navigate to System Security and create new users
- 3 Create support groups that represent different support teams
- 4 Create roles that define permissions for users
- 5 Create a custom table called Operations Related to store ticket information
- 6 Configure Access Control Lists to manage security permissions
- 7 Use Flow Designer to create automation flows that assign tickets automatically

5. System Modules

- **User Management Module:** This module allows administrators to create and maintain user accounts. Each user can be assigned specific roles and groups based on their responsibilities within the organization.
- **Group Management Module:** Support groups are created to represent teams responsible for handling specific categories of issues. For example, a platform group may handle login issues while a certificate group handles certification related problems.
- **Role Management Module:** Roles determine what actions a user can perform within the system. By assigning roles to users, administrators can control access to sensitive operations.
- **Ticket Management Module:** This module is responsible for creating, storing, updating, and tracking support tickets submitted by users.
- **Automation Module:** Automation flows created using ServiceNow Flow Designer automatically route tickets to the appropriate group based on predefined conditions.

6. Running the System

- 1 Login to the ServiceNow platform
- 2 Navigate to the Operations Related table
- 3 Create a new support ticket
- 4 Select the appropriate issue category
- 5 Submit the ticket
- 6 The system automatically assigns the ticket to the relevant support group
- 7 Support team members review and resolve the issue

7. Security and Authentication

Security is a critical aspect of the system. Role-based access control ensures that only authorized users can perform specific actions within the platform. Access Control Lists (ACL) are used to define permissions for reading, writing, or modifying records. This ensures that sensitive data is protected and only accessible to appropriate users.

8. Testing

- Unit testing to verify individual modules such as user creation and group assignment
- System testing to validate the entire ticket routing workflow
- Manual testing to ensure correct automation behavior
- Edge case testing to check system response to incorrect inputs

9. Known Issues

If incorrect issue categories are selected, the ticket may be routed to the wrong support group. Proper configuration of flows and roles is required to maintain system accuracy.

10. Future Enhancements

- Integration with artificial intelligence for automatic issue classification
- Email integration to automatically convert emails into tickets
- Mobile notifications for support teams
- Advanced reporting dashboards
- Automatic escalation for unresolved tickets

11. Conclusion

The automated ticket assignment system improves the efficiency of support operations by eliminating the need for manual ticket routing. Using ServiceNow automation tools, tickets can be processed quickly and assigned to the appropriate teams. This leads to faster issue resolution, better workload distribution, and higher customer satisfaction.
